

Relationship & synergies between monitoring systems for carbon stock change and multiple benefits

Maurizio Teobaldelli, Nathalie Doswald & Barney Dickson

22-24 June 2010

MRV Joint Workshop

Guadalajara, Jalisco, México

REDD+, carbon & multiple benefits

- Implementing REDD+ will require a system to establish the success of the mitigation actions
- Monitoring & reporting carbon emissions, removals, carbon stock and forest area changes
- REDD+ can generate multiple benefits – but to understand what these are and how they change - monitor multiple benefits

REDD+, carbon & multiple benefits

- Which multiple benefits? How to monitor them? How to reduce cost burden?
- Are there any **relationships** between monitoring systems for carbon stock change and multiple benefits?
- Are there **synergies** between monitoring carbon stock change & multiple benefits?
- Should the two monitoring systems be distinct or combined into a single monitoring system?
- Should the monitoring system for multiple benefits be mandatory or voluntary?

Why a monitoring system For multiple benefits?

Decision 2/CP.13

Recognizing that reducing emissions from deforestation and forest degradation in developing countries can promote co-benefits and may complement the aims and objectives of other relevant international conventions and agreements,

Ad Hoc Working Group on Long-term Cooperative Action under the Convention Text to facilitate negotiations among Parties

Note by the Chair*

2. *Further affirms* that when undertaking activities referred to in paragraph 3 below, the following safeguards should be promoted and supported:

- (a) Actions complement or are consistent with the objectives of national forest programmes and relevant international conventions and agreements;
- (b) Transparent and effective national forest governance structures, taking into account national legislation and sovereignty;
- (c) Respect for the knowledge and rights of indigenous peoples and members of local communities, by taking into account relevant international obligations, national circumstances and laws, and noting that the General Assembly has adopted the United Nations Declaration on the Rights of Indigenous Peoples;
- (d) Full and effective participation of relevant stakeholders, including, in particular, indigenous peoples and local communities in actions referred to in paragraphs 3 and 5 below;
- (e) Actions that are consistent with the conservation of natural forests and biological diversity, ensuring that actions referred to in paragraph 3 below are not used for the conversion of natural forests, but are instead used to incentivize the protection and conservation of natural forests and their ecosystem services, and to enhance other social and environmental benefits;
- (f) Actions to address the risks of reversals;
- (g) Actions to reduce displacement of emissions;

Co-Benefits & Safeguards

Which multiple benefits?

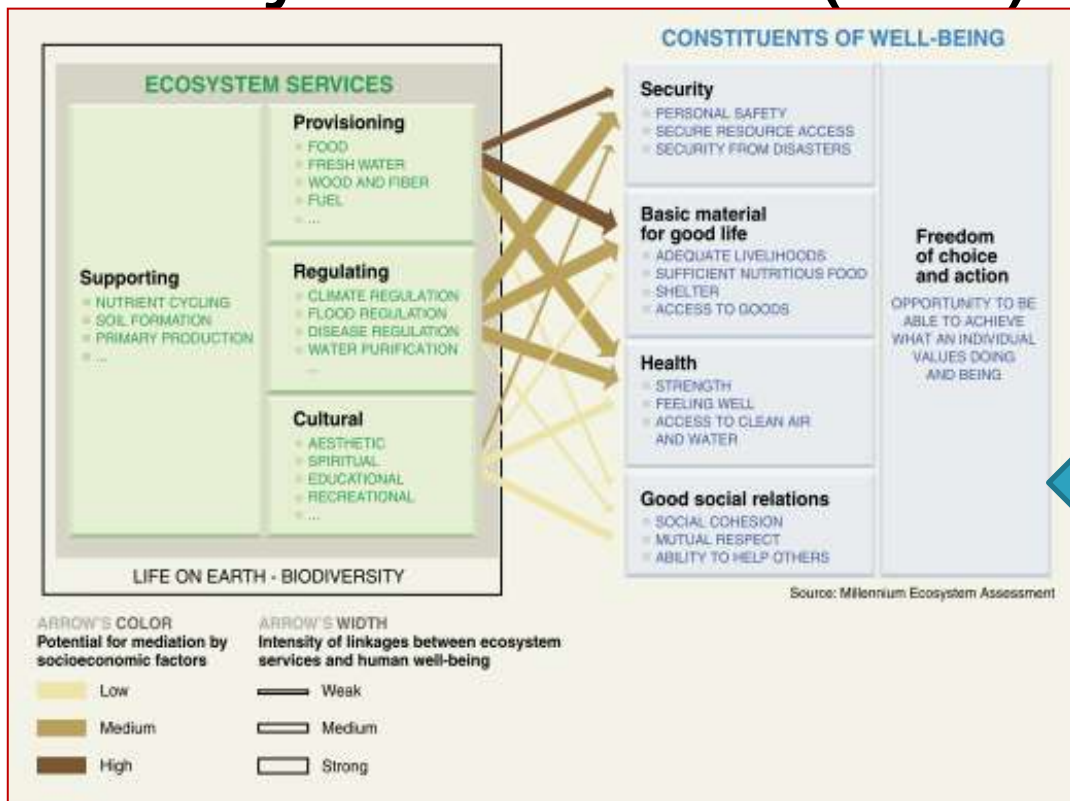

UN-REDD Programme

	International (UNFCCC) reporting requirements	Further National REDD implementation requirements, to be defined at country level
Carbon	Stock and changes of carbon pools in the six land use categories	Localized carbon information is required on carbon in ecosystems, landscape, species, and tree components for each category of land use, and tailored to national REDD implementation.
Multiple Benefits (co-benefits)	(Co-benefits Incentive Systems)	<p>Goods (Non-wood and wood products)</p> <p>Ecosystem and other services (biodiversity conservation, water conservation, soil Conservation, cultural and spiritual values, forest pasture)</p> <p>Uses and users of goods and services</p> <p>Socio-economic, livelihoods, food security and Poverty indicators</p> <p>Land tenure</p>

Indicative information requirements for REDD implementation, related to carbon, natural resources and their management and uses (Framework for Action 2009-2014 on MRV, UN-REDD Programme; May 2010)

Which multiple benefits?

Ecosystem services (MEA)

**Ecosystem
Aspects of
multiple
benefits**

Some networks or monitoring activities related to ecosystem services

International Initiatives

- GEO-BON (Global Earth Observation - Biodiversity Observation Network) & GEO-FCT (Forest Carbon Tracking);
- GFW, WRI (Global Forest Watch; World Resources Institute);
- GOFC-GOLD (Global Observation of Forest and Land Cover Dynamics);
- FRA, FAO (Global Forest Resources Assessments of the Food and Agricultural Organization of United Nations);
- ILTER (International Long Term Ecological Research Network)
- TEMS, GTOS (DBs of Terrestrial Ecosystem Monitoring Sites by the Global Terrestrial Observing System)
- IABIN (Inter-American Biodiversity Information Network);
- GBIF (Global Biodiversity Information facility);

National Initiatives

- NATIONAL FOREST INVENTORIES
- OTHER MONITORING SYSTEMS
 - Satellite Land Monitoring System;
 - National Environmental Agencies;
 - Water Resources Agencies
 - Independent Monitoring Systems
- LTER (Long Term Ecological Research Network)
- LOCAL COMMUNITY MONITORING

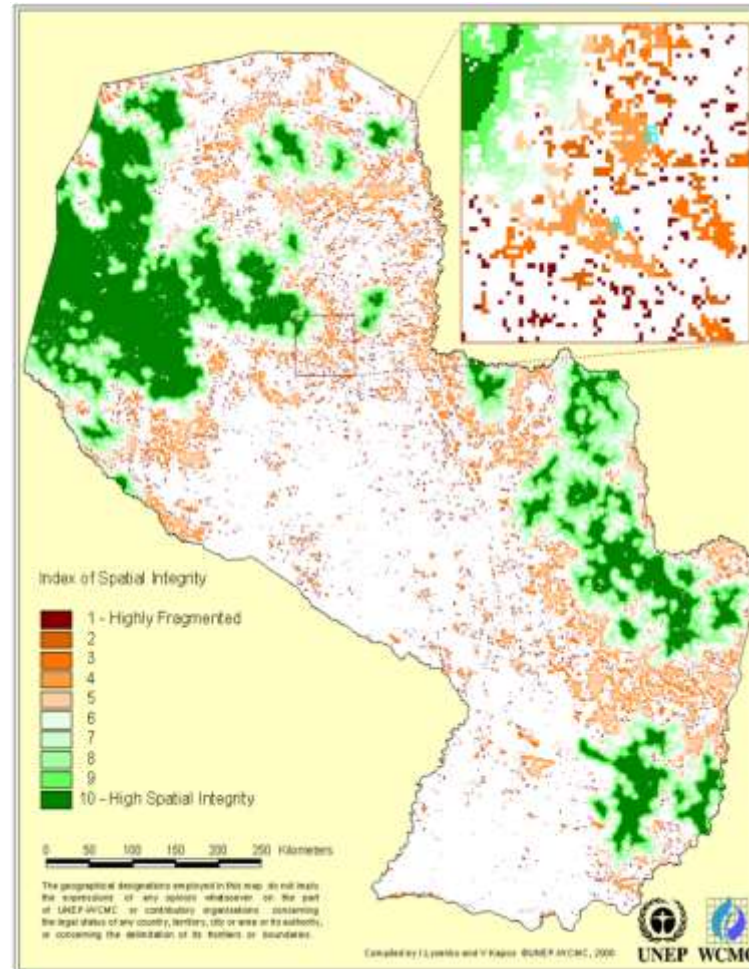

Biodiversity

***“Technological advances, refined methodologies and growing databases make our systems for monitoring biodiversity increasingly effective”....
“remote sensing is without a doubt one of the indispensable tools for detecting changes in multiple facets of biodiversity over time”***

Forest Fragmentation

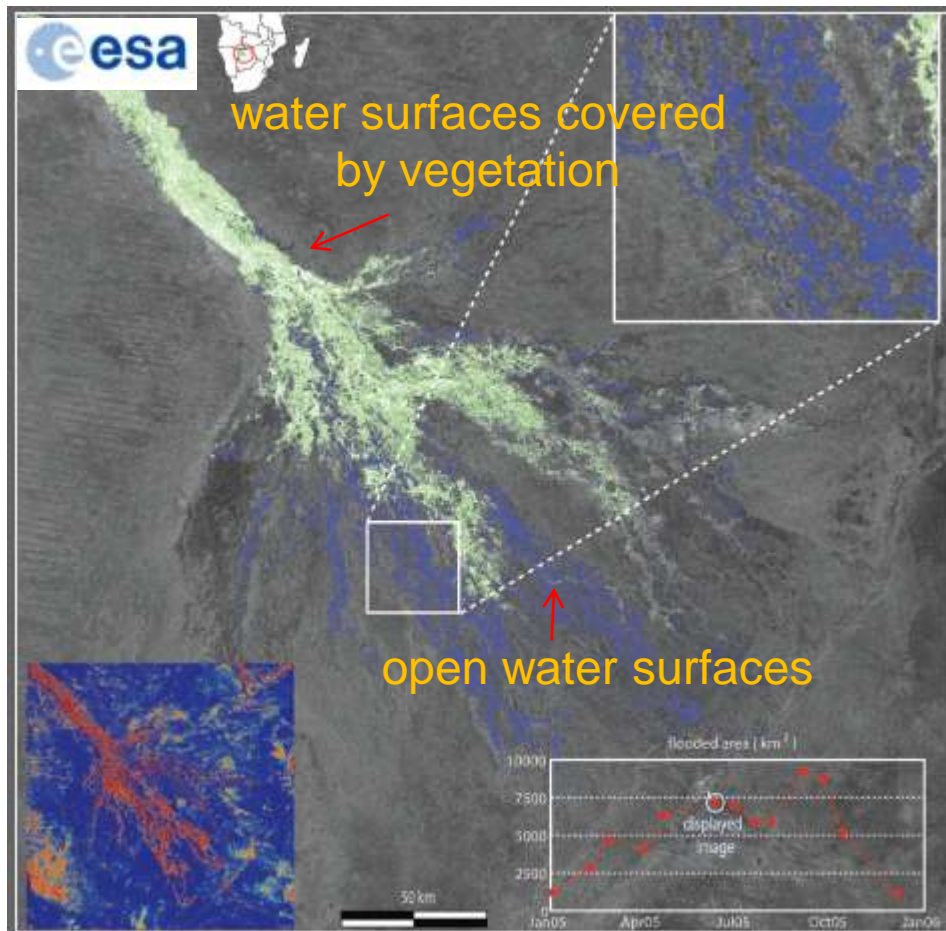

The forest cover of Paraguay displayed by integrity classes derived from the index of Forest Spatial Integrity

Kapos et al. 2000

Flooding patterns

Flooding patterns of the Okavango Delta (Botswana) from Envisat Advanced Synthetic Aperture Radar (ASAR) time-series.

Water turbidity

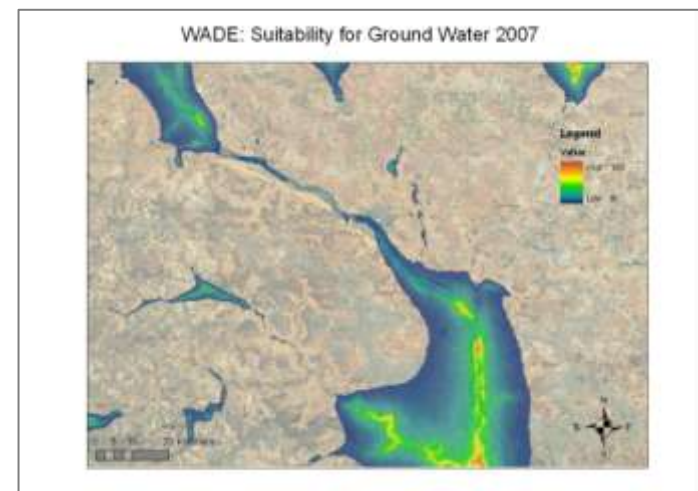

Relative **water turbidity** over the Lake Manzalah area in Egypt derived from Envisat MEdium Resolution Imaging Spectrometer (MERIS).

Water Map & Ground Water Suitability

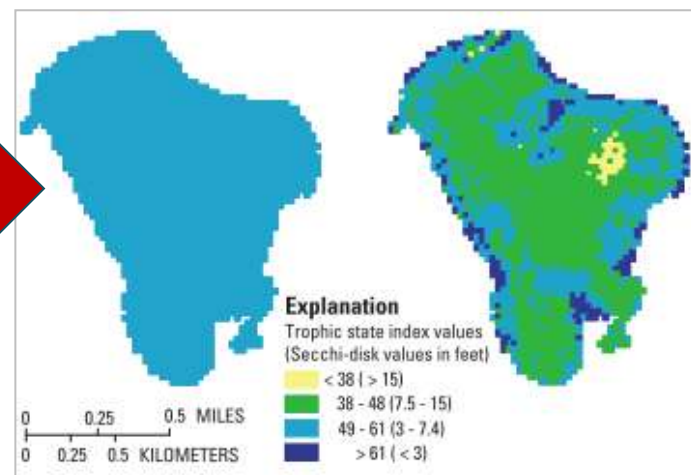

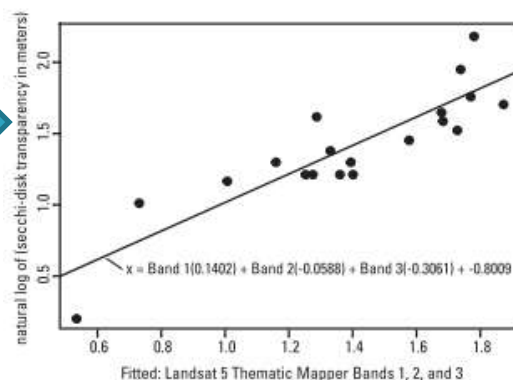

Synthetic Aperture Radar (SAR) data from ESA's Envisat and ERS satellites over the Niger River.

Lake trophic states

Lake trophic states and classification ranges for:

- trophic state index
- total phosphorus
- Secchi-disk transparency
- chlorophyll a.

Information averaged from nine cells surrounding a 2002 Secchi-disk transparency (SDT) measurement from a 2002 Landsat 5 TM satellite image of Lake Lansing, Michigan (USGS 2007).

Relationships

Monitoring carbon stock changes for REDD+

Monitoring carbon stock change requires assessing:

- (1) Location: i.e. land unit (ha); land use categories; carbon pools
- (2) Quantification: carbon density (carbon ha⁻¹) and carbon stock (stratified by eco-regions, forest type, C pools)
- (3) Changes: quantitatively variation of carbon stock over time

Monitoring carbon stock changes for REDD+

- different REDD+ activities and LULUCF
- different carbon pools & tier level
- different parameters/indicators all related to carbon

➡ IPCC guidance

➡ Remote sensing & ground-based inventories with different resolution, intensity & time frame (e.g. NFIs repeated every 5 yrs)

Monitoring changes of ecosystem aspects of multiple benefits for REDD+

Monitoring ecosystem aspects of multiple benefits requires assessing:

- (1) **Location** : land unit (ha); eco-region; ecosystem; forest type; niche
- (2) **Quantification**: quantity/quality of ecosystem aspects of multiple benefits (**info could be also stratified**)
- (3) **Changes**: quantitative or qualitative variation of ecosystem aspects of multiple benefits

Monitoring changes of ecosystem aspects of multiple benefits for REDD+

- different natural & human-induced activities (including also REDD+ activities) & LULUCF
- *Different parameters/indicators related to different ecosystem services (biodiversity, timber, NTFPs, soil, water, etc.)*

➡ No agreed standards

➡ **Remote sensing & ground-based measurements** with different resolution, intensity & time frame

Monitoring changes of ecosystem aspects of multiple benefits for REDD+

		Carbon stock	Ecosystem aspects of multiple benefits
REMOTE SENSING	Coarse to medium resolution	e.g. land use categories, forest cover, deforestation, etc.	e.g. topography, forest cover and location and boundaries of different ecosystem and resources, etc.
	High resolution	e.g. Forest degradation; conservation and enhancement of forest carbon stock, etc.	e.g. Forest fragmentation; continuity of streams, etc.
	Multispectral Imagery	e.g. Forest type or species differentiation, Indicator of growth rate, vegetation cover and density, NDVI, soil types, etc.	e.g. composition and thermal properties of ground, turbidity, temperature or pollution of lake and/or river, etc.
	RADAR/ LiDAR	biomass; tree height	Degree of vulnerability of land to floods, landslide, erosion or subsidence, etc.
GROUND-BASED MEASUREMENTS		Calibration of RS; additional information (DBH, carbon pools; allometric equations; BECF), etc.	timber; NTFPs; biodiversity; soil, water and air quality, etc.

Carbon, biodiversity and ecosystem services: exploring co-benefits

Honduras

UNEP WCMC

Why map carbon, biodiversity and ecosystem services?

Ecosystems have lost one third, mainly forest loss, contribute 13.2% of total anthropogenic greenhouse gas emissions (IPCC 2007). The UN Framework Convention on Climate Change is currently balancing incentives for Reducing Emissions from Deforestation and forest Degradation in Developing countries (REDD). In addition to securing carbon, REDD can deliver co-benefits, including conservation of forest biodiversity and management of ecosystem services. To help secure co-benefits, it is useful to find out where high carbon, high biodiversity priority and ecosystem service areas overlap.

Data and methods

The first available spatial data for Honduras on ecosystem cover, biodiversity and protected areas were compiled. Two national scale data on carbon stocks were derived from the inventory cover data and global soil carbon data. The data were combined in a Geographic Information System and statistical analyses were run to address questions such as:

- How much carbon is stored in Honduras' ecosystems?
- How does carbon storage relate to areas of biodiversity priority?
- How much carbon is stored in protected areas?

Results

- Carbon:** The ecosystems of Honduras store approximately 1.9 Gt of carbon in their biomass and soil, and the mean carbon stock (t/ha) of the country falls over a third of the world carbon stock.
- Carbon and areas of biodiversity priority:** Two approaches were used to identify biodiversity priorities:
 - Threatened species:** 4% of the land area of Honduras is high in both carbon and threatened species distributions of threatened species. Such high priority areas hold 50% of the country's total carbon. As 23% of the area important for threatened species has low carbon storage, some threatened species may be affected by pressure imposed by reducing land use change to high carbon areas.
 - High Biodiversity Areas (HBAs):** These places of international importance for the conservation of biodiversity cover 30% of Honduras' land area and 20% of its total carbon stock.
- Carbon and protected areas (PAs):** In Honduras PAs cover 18% of the land area and 27% of the country's carbon stock. 43% of the areas with the highest carbon stocks are protected (23% in IUCN Category II PAs). The lower 50% of land that is high both in carbon and in threatened species distributions, and 67% of HBAs, High biodiversity priority areas that are low in carbon and poorly protected and may be vulnerable to deforestation pressure.

Conclusions and outlook

Although nearly half of the areas in Honduras with the highest carbon stocks have some degree of protection, less than one third of the country's substantial total ecosystem carbon stores are within the protected areas included in this analysis. More than half of those areas that are high in both biodiversity priority and carbon stocks are protected, but some remain unmet for biodiversity. These low carbon stocks and are unlikely to be priority areas for REDD. Such information is important to support decision-making about REDD and its benefits. Improving data on carbon stocks and increasing information of ecosystem services will be the next steps for ensuring that REDD delivers in Honduras the maximum of a full range of benefits.

Synergies

Monitoring system for carbon stock change in REDD+

REDD+IA: REDD+ Impact Assessment
NFI: National forest inventory; **AD:** Activity Data;;
EF: Emission Factor; **E.E:** Emission Estimate

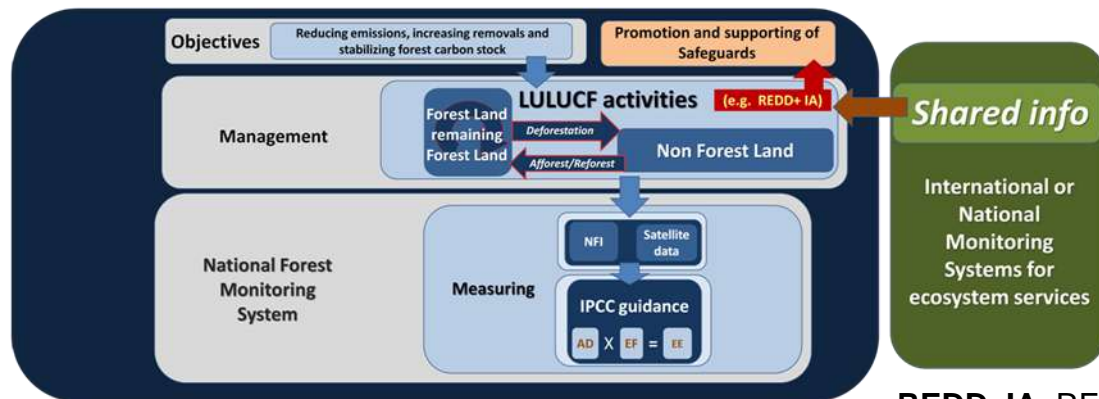

Monitoring system for carbon stock change in REDD+

Clarity:

- Objectives of external monitoring system of ecosystem aspects of multiple benefits are not necessarily directed toward meeting REDD+ objectives;

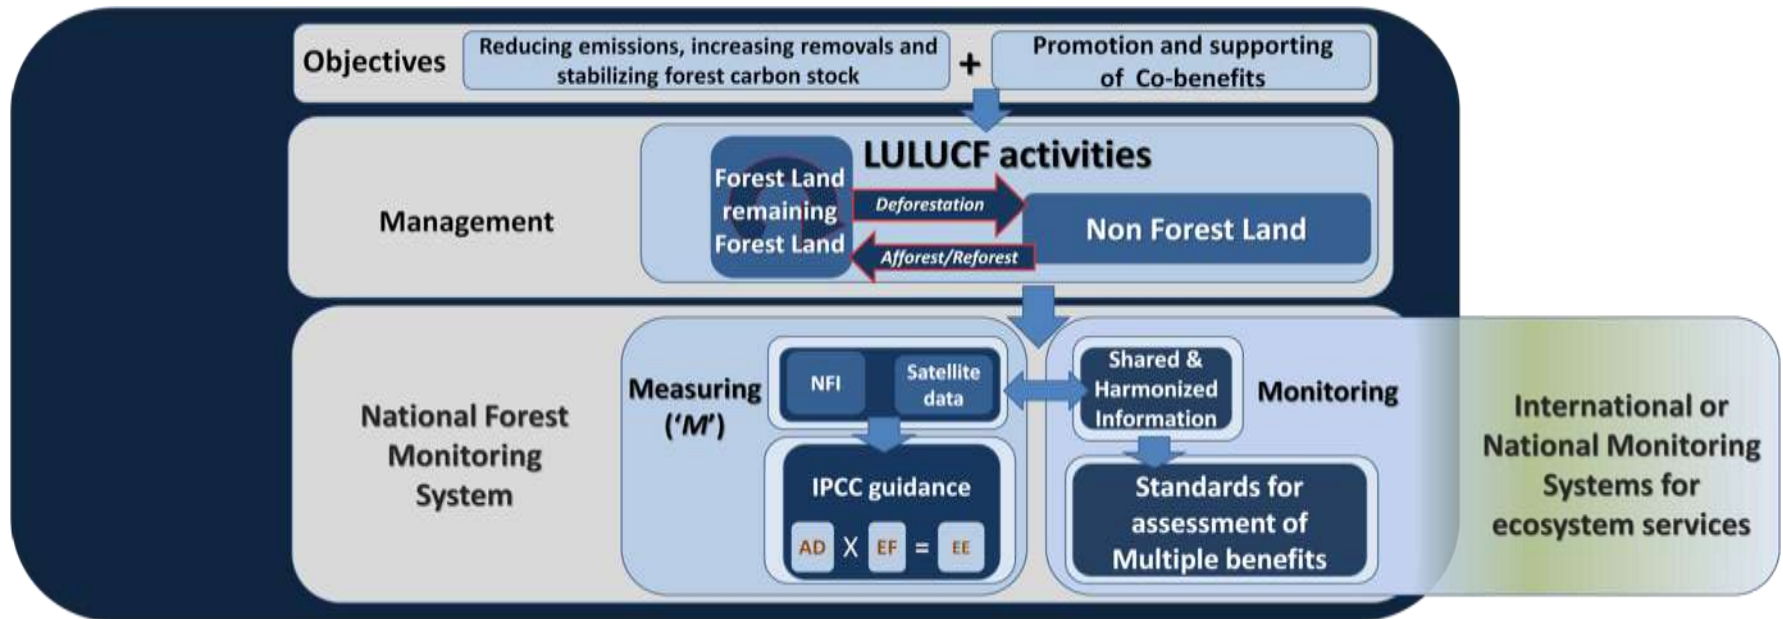

Effectiveness :

- External monitoring systems of ecosystem services do not benefit from resources (e.g. RS and NFIs) utilised within the monitoring system for carbon stock change but these initiatives could provide information useful to support and promote safeguards;

REDD+IA: REDD+ Impact Assessment
NFI: National forest inventory; **AD:** Activity Data;;
EF: Emission Factor; **E.E:** Emission Estimate

Monitoring system for carbon stock change and ecosystem aspects of multiple benefits in REDD+

NFI: National forest inventory; **AD:** Activity Data; **EF:** Emission Factor; **EE:** Emission Estimate

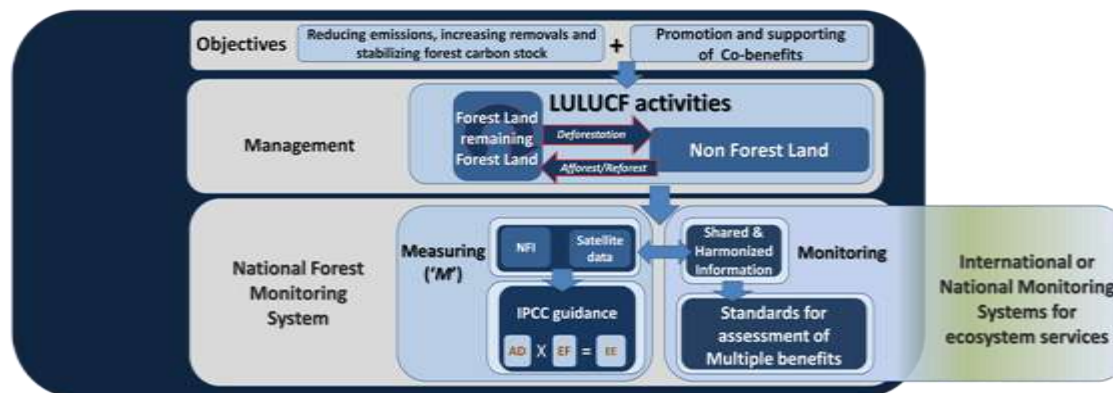

Monitoring system for carbon stock change and ecosystem aspects of multiple benefits in REDD+

Clarity:

- Objectives of a combined monitoring system for carbon stock and ecosystem aspects of multiple benefits are directed toward meeting REDD+ objectives

Effectiveness:

- Resources are used effectively in the combined system;
 - External monitoring systems for ecosystem services could inform the monitoring system in REDD+ but they can also benefit from shared and **harmonized** information coming from the combined monitoring system

NFI: National forest inventory; AD: Activity Data;
 EF: Emission Factor; EE: Emission Estimate

Difficulties in monitoring ecosystem aspects of multiple benefits in REDD+

Monitoring ecosystem aspect of multiple benefits requires assessing different parameters & indicators

- Not all the ecosystem aspects of multiple benefits are measurable or have enough data
- difficulties in identifying drivers of changes linked with REDD+
- Resolution (implementation phases)
- No agreed standards
- Resources limited and in REDD+ for carbon assessment
- Current initiatives information may not match up

Conclusions

Conclusions

- There are **clear relationships** between monitoring systems for carbon stock change and ecosystem aspects of multiple benefits;
- Carbon stock change assessment uses agreed standards (IPCC) and it refers to land use and some forest and soil characteristics **which may also be used for assessing changes of ecosystem aspects of multiple benefits**
- Multiple benefits are **multidimensional concepts** and **monitoring is challenging** (timber; NFTP's; soil; water; air; etc.); **methodologies are various** and generally they belong to the field of interest
- However, RS and ground-based measurements are used to detect and quantify variables in both monitoring systems.

Conclusions

- 
- A mandatory monitoring system for ecosystem aspects of multiple benefits may require agreed standards (methods)
 - Nevertheless there are numerous ongoing initiatives related to ecosystem services at international, national or local level which may benefit REDD+
 - Although external monitoring system for ecosystem services may inform REDD+, **synergies may be less effective if objectives of monitoring are different and resources are not shared in an integrated and effective way**
 - In REDD+ a combined monitoring system for ecosystem aspects of multiple benefits may be costly although it may be more effective to achieve REDD+ objectives and to promote other international agreements and conventions

Summary

Relationship between carbon stock change monitoring and ecosystem aspects of multiple benefit monitoring

Synergies depend on implementation of monitoring system, whether combined or not

Monitoring ecosystem aspects of multiple benefits is still challenging as other indicators and standards need to be established
